- <span id="page-1-0"></span>**.** Video dominates Internet traffic
	- $\bullet$  In 2016, Youtube was responsible for %21 of mobile Internet traffic in North America (Sandvine 2016).
	- By 2021 size of Internet video traffic will be 4 times larger (Cisco 2017).
- Small number of viral video files are viewed by many users.
- Decreasing cost of high capacity storage.
- Densification of small-cells: mobility-aware coded storage

E. Ozfatura and D. Gunduz, Mobility and popularity-aware coded small-cell caching, IEEE Communications Letters, vol. 22, no. 2, pp. 288 - [29](#page-0-0)1[, F](#page-2-0)[e](#page-0-0)[b.](#page-1-0) [2](#page-2-0)[0](#page-0-0)[18.](#page-1-0)  $299$

<span id="page-2-0"></span>

- One macro base station (MBS)
- $\bullet$  N small-cell base stations (SBSs) with a cache memory of size C bits.
- Library of K files,  $\mathbb{V} = \{v_1, \ldots, v_K\}$ , each of size F bits.
- $v_k$  is the kth most popular file with request probability  $p_k$ .
- Within one time slot. MU can download B bits from a SBS.
- Duration of one streaming session:  $T = F/B$  $T = F/B$  [sl](#page-3-0)[ot](#page-1-0)[s.](#page-2-0)

つひひ

- <span id="page-3-0"></span>Mobility path: Sequence of SBSs visited within one streaming session.
- High mobility scenario: A mobile user (MU) connects to each SBS at most one time slot; that is, MU connects to  $T$  SBSs within one streaming session.
- Video display rate  $\lambda = B$ , i.e., it takes T time slots to play the downloaded file.
- Display can start before downloading all the segments of a file.
- Buffer starvation: MU buffer is empty.
- Rebuffering delay: When buffer starvation occurrs video display is frozen until next segment is downloaded.

## <span id="page-4-0"></span>Maximum Distance Separable (MDS) Codes

Figure: (2,4) MDS code

- Consider 4 SBSs and a user that can connect to any 2 over time  $(T = 2)$ .
- Each file is divided into 2 fragments. Fragments are encoded into 4 fragments through a (2, 4) MDS code.
- Each SBS caches a different coded fragment.
- User can recover the file by connecting to [any](#page-3-0) [2](#page-5-0)[SB](#page-4-0)[S](#page-5-0)[s](#page-1-0)[.](#page-2-0)

## <span id="page-5-0"></span>Conventional Coded Storage

Figure: Video streaming process with conventional coded storage for  $T = 9$ 

- $\bullet$  Each file divided into T segments, and coded with  $(T, N)$  MDS code.
- Each SBS stores one coded segment  $(F/T)$  bits) for each file.
- Rebuffering delay is  $T$  time slots

## <span id="page-6-0"></span>Delay-Aware Encoding

Figure: Video encoding for  $T = 9$  and  $M = 3$ 

- $\bullet$  Segments are grouped into M disjoint fragments.
- $\bullet$  Segments in each fragment are encoded wi[th](#page-5-0) $(T/M, N)$  M[D](#page-2-0)[S](#page-16-0) [co](#page-0-0)[de](#page-16-0).

### <span id="page-7-0"></span>Delay-aware Coded Storage

Figure: Video streaming with delay-aware coded storage for  $T = 9$  and  $M = 3$ 

• Each SBS stores  $MF/T = MB$  bits for each file, and rebuffering delay is  $\lceil T/M \rceil$  time slots

- <span id="page-8-0"></span>• Delay-cache capacity function  $\Omega(M) \triangleq \lfloor T/M \rfloor$ : maps the number of fragments M to the rebuffering delay  $D \in \mathcal{Z}^+$  (slots).
- $\Omega(M)$  is a monotonically decreasing step function.
- Delay levels,  $D^{(l)}$ : Possible values taken by  $\Omega(M)$ .
- Decrement points,  $m^{(1)}$ : minimum M that satisfies  $\Omega(M) = D^{(1)}$

### <span id="page-9-0"></span>Delay-Memory trade-off

Figure: Delay-cache capacity function and its piece-wise linear approximation for  $T = 10$ 

• 
$$
D^{(1)} = 10
$$
,  $D^{(2)} = 5$ ,  $D^{(3)} = 4$ ,  $D^{(4)} = 3$ ,  $D^{(5)} = 2$ ,  $D^{(6)} = 1$ 

• 
$$
m^{(1)} = 1
$$
,  $m^{(2)} = 2$ ,  $m^{(3)} = 3$ ,  $m^{(4)} = 4$ ,  $m^{(5)} = 5$ ,  $m^{(6)} = 10$ 

### <span id="page-10-0"></span>Problem Formulation

 $\bullet$  For file  $v_k$ , expected delay-cache capacity function:

 $\Omega_k(M_k) \triangleq p_k [T/M_k]$ 

• Average rebuffering delay,  $\mathbf{M} = (M_1, \ldots, M_K)$ 

$$
D_{\text{avg}}(\mathbf{M}) = \sum_{k=1}^{K} \Omega_k(M_k)
$$

 $\bullet$   $D_{\text{max}}$ : Maximum allowable delay for a video file.

P1: 
$$
\min_{\mathsf{M}} D_{\text{avg}}(\mathsf{M})
$$
  
subject to:  $D_k(M_k) \leq D_{\text{max}}, \forall k$ ,  

$$
\sum_{k=1}^K M_K B \leq C.
$$

# Solution Approach

#### **Observation**

- Replacing  $\Omega_k(M_k)$  with its linear approximation  $\tilde{\Omega}_k(M_k)$ , <code>P1</code> becomes a convex optimization problem
- Let  $\gamma_{k,l}$  be the slope of  $\tilde{\Omega}_k(M_K)$  in interval  $(m^{(l)},m^{(l+1)}]$ , and an approximately optimal solution found in polynomial time by sorting  $\gamma_{k,l}$

#### Lemma

- Approximate solution is equivalent to the optimal if  $M_k$  is equal to some decrement point  $m^{(l_k)}$  for each  $k_\cdot$
- Otherwise, the optimal solution can obtained by increasing cache size C by at most  $\epsilon \leq F/2$ .

## Cost-Aware Delay-Constrained Caching

#### Problem Definition

- It may not be possible to satisfy maximum delay constraint  $D_{max}$  for all files.
- We can also impose a QoS constraint  $D_{max}$  on  $D_{ave}(\mathbf{M})$ .
- Some files not cached at SBSs and served directly by MBS with an additional cost.
- $\bullet$  Objective: Minimize cost while satisfying constraints  $D_{max}$  and  $D_{max}$

### Solution Approach

• At each iteration remove the least popular file and apply the delay-aware coded caching method. Continue until constraints  $D_{max}$ and  $D_{max}$  are met.

• Cache most popular files: First, all files are cached to meet  $D_{max}$ , then starting from the most popular file, rebuffering delays are sequentially reduced to minimum.

Cache files equally: All files are cached with same delay.

## Minimizing Average Rebuffering Delay

Figure: Average buffering delay versus cache size for  $D_{max} = 10$  slots

- Video library of 10000 files: popularity is modeled using a Zipf distribution with coefficient  $w \in \{0.75, 0.85, 0.95\}.$
- Video download duration  $T = 10$  slots, and  $D_{max} = 10$  time slots.
- Consider cache sizes  $\hat{C}$  ∈ [0.1, 0.7].

### <span id="page-15-0"></span>Minimizing Average Cost

Figure: Average cost versus maximum average delay constraint for  $T = 10$  slots

• Set cache size 
$$
\hat{C} = 0.08
$$
 and  $D_{\text{max}} = 10$ .

• Consider  $\overline{D}_{max} \in [2, 8]$ .

- <span id="page-16-0"></span>Analyzed storage-delay trade-off focusing on continuous video streaming.
- Introduced fragment-based coded caching to reduce rebuffering delay
- **•** Future directions:
	- Consider more general user mobility models.
	- Consider a video display rate higher than the download rate from SBSs.
